

# Design pattern: Composite

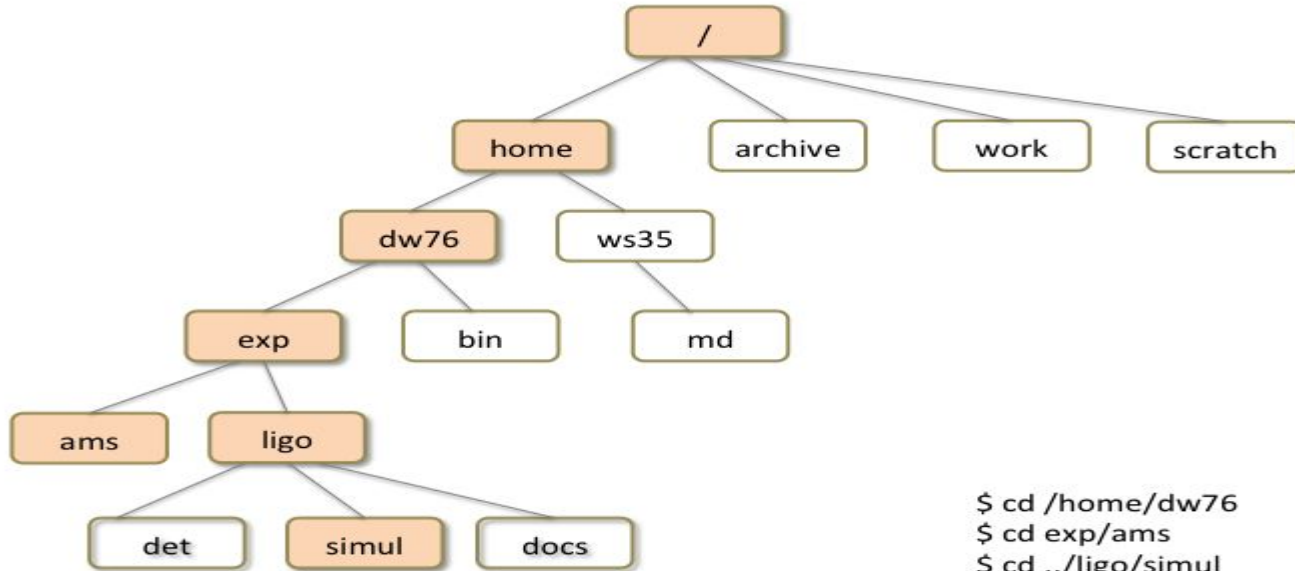

Gabriel Ferreira Cerqueira

# Problem

Think about: How computer directories can be set? And what about their similarities with an ordinary program?

# System directory tree

```
$ cd /home/dw76  
$ cd exp/ams  
$ cd ../ligo/simul
```

# Motivation

- Using composite pattern allows:
  - You to compose objects into tree hierarchical structures
  - The client to treat different types of objects uniformly.

# Different classes for different types

## Directories

-name: String  
-size: Float  
-type: String  
-Path: String  
-directoryComponents: Arraylist

+getName(): String  
+getSize(): String  
+getType(): String  
+getPath(): String  
+getComponent(): ?  
+setName(): Void  
+setSize(): Void  
+setType(): Void  
+setPath(): Void  
+addComponent(): Void  
+removeComponent(): Void

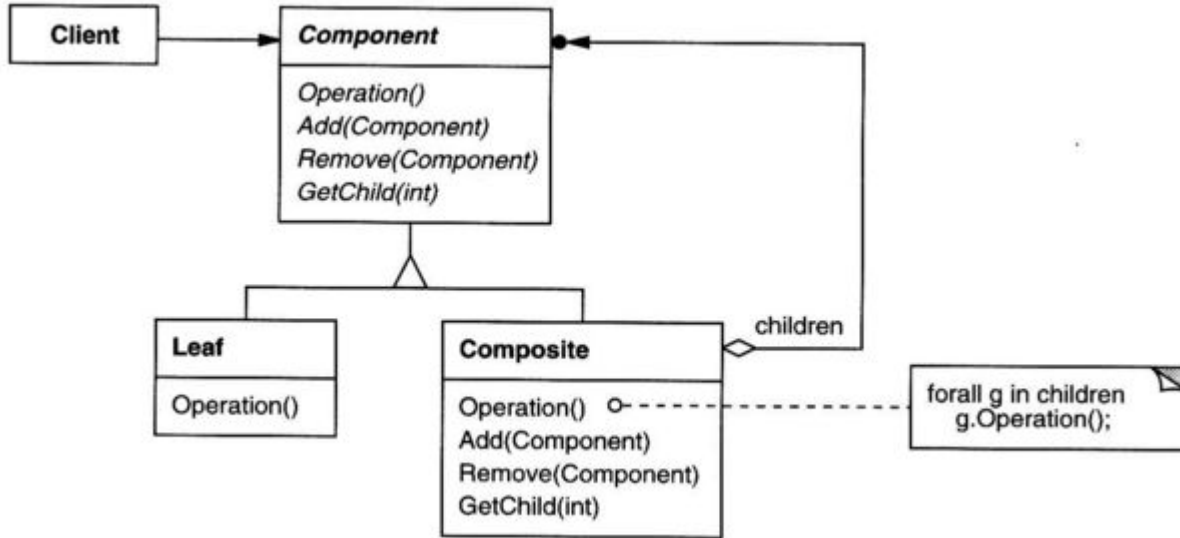

## Programs

-name: String  
-size: Float  
-type: String

+getName(): String  
+getSize():String  
+getType():String  
+getPath(): String  
+setName(): Void  
+setSize(): Void  
+setType(): Void  
+setPath(): Void

# The Composite pattern

# Applying the pattern

```
public abstract class DirectoryComponent {  
  
    public void getName(){throw new UnsupportedOperationException();}  
  
    public void getSize(){throw new UnsupportedOperationException();}  
  
    public void getType(){throw new UnsupportedOperationException();}  
  
    public void getPath(){throw new UnsupportedOperationException();}  
  
    public void getcomponent(){throw new UnsupportedOperationException();}  
  
    public void setSize(){throw new UnsupportedOperationException();}  
  
    public void setType(){throw new UnsupportedOperationException();}  
  
    public void setPath(){throw new UnsupportedOperationException();}  
  
    public void addComponent(){throw new UnsupportedOperationException();}  
  
    public void removeComponent(){throw new UnsupportedOperationException();}  
  
}
```

# Applying the pattern

```
public class Directory {  
    private String name, type, path;  
    private float size;  
    private ArrayList <DirectoryComponent>;  
  
    public void Directory(...){}  
  
    public String getName(){// override method}  
  
    public float getSize(){// override method}  
  
    public String getType(){// override method}  
  
    public String getPath(){// override method}  
  
    public DirectoryComponent getcomponent(){// override method}  
  
    public void setName(...){// override method}  
  
    public void setSize(...){// override method}  
  
    public void setType(...){// override method}  
  
    public void setPath(...){// override method}  
  
    public void addComponent(...){t// override method}  
    public void removeComponent(...){// override method}  
}
```

# Applying the pattern

```
public class Program {  
    private String name, type, path;  
    private float size;  
  
    public void Program(...){}  
  
    public String getName(){// override method}  
  
    public float getSize(){// override method}  
  
    public String getType(){// override method}  
  
    public String getPath(){// override method}  
  
    public void setName(...){// override method}  
  
    public void setSize(...){// override method}  
  
    public void setType(...){// override method}  
  
    public void setPath(...){// override method}
```
